Abstract

The radical complex, $(C_5Ph_5)Cr(CO)_3$, reacts with small, neutral, monodentate Lewis bases (PMe_3 , PMe_2Ph , and $P(OMe)_3$) in THF at $-78\text{ }^\circ\text{C}$ (PMe_2Ph reacts at ambient temperature) to yield the monomeric substitution products, $(C_5Ph_5)Cr(CO)_2L\cdot THF$ as thermally stable solids. Electrochemical and spectroscopic data are provided. An X-ray crystal structure of the hemisolvate $(C_5Ph_5)Cr(CO)_2PMe_3\cdot 0.5THF$ was obtained. Frozen solution ESR spectra of $(C_5Ph_5)Cr(CO)_2L$ in toluene are comparable to those of other low-spin d^5 "piano-stool" complexes. Rotation of the $Cr(CO)_2L$ moiety relative to the C_5Ph_5 ring is rapid on the ESR time scale in low-temperature liquid solutions and leads to axial powder-like spectra. Analysis of this effect leads to significant insights into the electronic structure.

Introduction

Over the past two decades, the study of paramagnetic organometallic complexes has greatly expanded.² These complexes are generally highly reactive and many have been postulated as reaction intermediates. In particular, the $(C_5R_5)Cr(CO)_3$ ($R = H, Me, Ph$) family of complexes recently has received much attention. The $R = H$ and Me complexes both exist in equilibria between 17e monomers and 18e dimers in solution and as dimers in the solid state,³ while for $R = Ph$ the complex exists solely as a 17e monomer both in solution and the solid state.⁴

Seventeen electron complexes containing CO ligands frequently undergo substitution reactions under mild conditions.^{5,6} The reactions tend to proceed via associative mechanisms⁷ because of incompletely filled sets of bonding molecular orbitals.⁸ Baird and coworkers have studied extensively the substitution reactions of $(C_5R_5)Cr(CO)_3$ ($R = H,$ ⁹ Me ^{10,9e}) with phosphines. Where $R = H$ (Cp) isolation of a product complex requires larger phosphines, while for $R = Me$ (Cp^*) only smaller phosphines replace CO in the starting complex.

The very large size of the C_5Ph_5 ligand should significantly restrict the size of substituents that can substitute CO in $(C_5Ph_5)Cr(CO)_3$, **1**. Three small, monodentate Lewis bases, PMe_3 , PMe_2Ph , and $P(OMe)_3$, react with **1** to yield isolable products, $(C_5Ph_5)Cr(CO)_2L$. These compounds have been spectroscopically and electrochemically characterized.

There have been many ESR studies of low-spin d^5 “piano-stool” complexes such as $(C_5R_5)Cr(CO)_{3-x}L_x$ ($R = H, Me$), $[(Arene)Cr(CO)_{3-x}L_x]^+$, and $Mn(II)$ analogs.¹¹ As we will show, the ESR spectra of $(C_5Ph_5)Cr(CO)_2L$ fit comfortably into the general scheme for these complexes and are thus rather unremarkable. However, the unique steric bulk of the C_5Ph_5 ligand leads to selective averaging of anisotropies in the ESR spectra of low-temperature liquid solutions, and parameters obtained from such spectra provide insights into the electronic structure which were unavailable in previous studies.

Experimental Section

General Data. All reactions of air- and moisture-sensitive materials were performed under

a nitrogen atmosphere employing standard Schlenk techniques unless otherwise stated. Solids were manipulated under nitrogen or argon in a Vacuum Atmospheres glovebox equipped with a HE-493 dri-train. Solvents (Fisher) were distilled from the appropriate drying agent under argon: toluene, hexane (sodium/benzophenone), benzene, tetrahydrofuran (THF) (potassium/benzophenone), and dichloromethane (CaH_2). $(\text{C}_5\text{Ph}_5)\text{Cr}(\text{CO})_3 \cdot \text{C}_6\text{H}_6$ was prepared according to a literature procedure.⁴ NMR solvents were vacuum distilled from CaH_2 and placed under an argon atmosphere. PPh_3 (PCR) was recrystallized from 95% ethanol. PMe_3 , PMe_2Ph , $\text{P}(\text{OMe})_3$, $\text{P}(\text{OPh})_3$ (Strem), CDCl_3 , CD_2Cl_2 (Aldrich), 2,2'-bipyridine (Matheson), diphenylacetylene (Eastman), and all other solvents (Fisher) were used without further purification. Elemental analyses were performed by Schwartzkopf Microanalytical Laboratory, Woodside, N.Y and Mikroanalytisches Labor Pascher, Remagen, Germany. ^1H (200.06 MHz) and ^{31}P (80.962 MHz) NMR spectra were obtained on a Varian XL-200 NMR spectrometer equipped with a Motorola data system upgrade.

Electrochemistry. Electrochemical data were obtained on a EG&G PAR VersaStat Model 250-1 Electrochemical Analysis system. The apparatus was maintained on a bench top under constant nitrogen purge. Freshly distilled CH_2Cl_2 was employed as the solvent, with a supporting electrolyte of 0.1 M $^n\text{Bu}_4\text{NPF}_6$ (recrystallized from 95% ethanol). Solutions were *ca.* 3 mM in complex.¹² Decamethylferrocene was added as an internal reference. Potentials are referred to the ferrocene/ferrocenium couple. All data were obtained with a Pt disk working electrode ($r = 1.6$ mm) and either a Ag/AgCl reference electrode or a AgCl coated Ag wire reference electrode.

ESR Spectroscopy. Electron spin resonance spectra were obtained using a Bruker ER-220D X-band spectrometer equipped with a Bruker variable temperature accessory, a Systron-Donner microwave frequency counter and a Bruker gaussmeter. Samples for ESR study were prepared in an argon-filled glove box by shaking the compound with degassed toluene to obtain a saturated solution; the solution was syringed into an ESR tube which was sealed with Parafilm before removal from the glove box. One series of spectra was obtained with 5 mg of the

P(OMe)₃ complex in 3 mL of 1:1 1,2-C₂H₄Cl₂/CH₂Cl₂ (dce/dcm); the solution was prepared in a glove box as before.

X-ray Structural Determination. Crystallographic data are summarized in Table 1. A specimen mounted on a glass fiber was found photographically to possess only triclinic symmetry. The centrosymmetric space group was initially assumed and later supported by the reasonable results of refinement. Variation in azimuthal scans were less than 10% and corrections for absorption were ignored. The structure was solved by direct methods. The asymmetric unit is composed of two crystallographically independent but chemically very similar molecules of the Cr complex and one molecule of THF. All non-hydrogen atoms were refined with anisotropic displacement parameters. Selected bond distances and angles are collected in Tables 2 and 3, respectively. Phenyl dihedral angles are presented in Table 4. All computations used SHELXTL 4.2 programs (G. Sheldrick, Siemens XRD, Madison, WI).

Low Temperature IR Spectroscopy. In a glovebag, a dilute solution of **1** in THF was cooled to -78 °C. Two equivalents of PMe₃ were added and the solution was allowed to warm until the blue solution turned to a green color. The solution was recooled to -78 °C, then transferred to a precooled IR cell via a precooled syringe (both at -78 °C). The color changes observed are the same as occur in synthetic scale reactions.

(C₅Ph₅)Cr(CO)₂PMe₃•THF (2). (C₅Ph₅)Cr(CO)₃•C₆H₆ (0.50 g, 0.76 mmol) was dissolved in 10 mL THF. The solution was then cooled to -78 °C and 0.21 mL PMe₃ (2.0 mmol) was added. The solution was allowed to warm to room temperature with stirring (*ca.* 1 h). As the dark blue solution warmed it initially turned a jade green color, then deep cherry-red. The solution was filtered via cannula and layered with 12 mL of hexane to yield **2** (0.48 g, 0.76 mmol) in 88% yield as dark red crystals: mp 211-218 °C (dec); ¹H NMR (C₆D₆) δ 7.32 (m, C₅Ph₅, br) 5.76 (s, PMe₃, br); visible λ_{max} (CH₂Cl₂) 516 nm. Anal. Calcd for C₄₄H₄₂CrO₃P: C, 75.31; H, 6.03. Found: C, 75.69; H, 5.79.

(C₅Ph₅)Cr(CO)₂PMe₂Ph•THF (3). (C₅Ph₅)Cr(CO)₃•C₆H₆ (0.50 g, 0.76 mmol) was dissolved in 10 mL THF and 0.50 mL PMe₂Ph (3.7 mmol) was added. The solution was stirred

overnight. The resulting red solution was filtered via cannula and layered with 12 mL of hexane to yield **3** (0.48 g, 0.76 mmol) in 72% yield as dark red crystals: mp 198-200 °C (dec); ¹H NMR (C₆D₆) δ 7.18 (m, C₅Ph₅ and P(Me₂Ph)₃, br), 5.49 (s, P(Me₂Ph)₃, br); visible λ_{max} (CH₂Cl₂) 470 nm (sh). Anal. Calcd for C₄₉H₄₄CrO₃P: C, 77.05; H, 5.81. Found: C, 76.54; H, 5.50.

(C₅Ph₅)Cr(CO)₂P(OMe)₃•THF (**4**). The procedure is the same as for **2** except that a magenta colored product is obtained in 90% yield: mp 188-192 °C (dec); ¹H NMR (C₆D₆) δ 7.34 (m, C₅Ph₅, br), 5.32 (s, P(OMe)₃, br); visible λ_{max} (CH₂Cl₂) 532 nm. Anal. Calcd for C₄₄H₄₂CrO₆P: C, 70.49; H, 5.65. Found: C, 71.05; H, 5.06.

Results and Discussion

Syntheses. Reaction of the (C₅Ph₅)Cr(CO)₃ radical with a variety of neutral, monodentate Lewis bases resulted in substitution products or no reaction between the materials depending on the ligand. The small, soft ligands PMe₃ and P(OMe)₃ react with (C₅Ph₅)Cr(CO)₃ in THF solution at low temperatures to yield the substitution products, (C₅Ph₅)Cr(CO)₂L (eq 1) as highly colored, crystalline materials in high yields (compounds **2** and **4**, respectively). PMe₂Ph reacts

with **1** at ambient temperature to yield this product (**3**) in slightly lower yields. The former reactions proceed very rapidly at ambient temperature, however isolated yields of the products are somewhat reduced. Unlike for CpMn(CO)₃⁺,^{6,13} no evidence for disubstitution of **1** was observed. All are air-sensitive, both in solution and in the solid state. ¹H NMR spectra were very broad and no resonances were observed in ³¹P NMR spectra of these compounds.

Infrared spectral and electrochemical data for these complexes are collected in Tables 5 and 6, respectively. A cyclic voltammogram of **2** is presented in Figure 1. The CO stretching frequencies and complex reduction potentials both follow the expected trends for the ligands. Two aspects of the electrochemical data are noteworthy. Replacing Cp by C₅Ph₅ in a complex usually results in potential shifts of *ca.* 0.2 V to more positive values.^{4,14} In contrast, the -1/0 couples for the PMe₃ and PMe₂Ph complexes show roughly the opposite trend. Hershberger and

Kochi examined a variety of (MeCp)Mn(CO)₂L complexes by cyclic voltammetry and found that replacing CO by PEt₃ and P(OMe)₃, resulted in potential shifts of -0.70 V and -0.42 V, respectively.¹⁵ For complexes **2** and **4** the shifts are -0.85 V and -0.54 V, respectively. Thus, the shifts in the reduction potentials of **2** and **4** relative to **1** are consistent with precedent. At ambient temperature, each complex also undergoes an irreversible oxidation approximately 1.3 V to more positive potential than the reversible reduction. The anodic waves equaled the cathodic waves in height within 20% in all cases and are also assigned as one-electron processes.

A low temperature (-78°) infrared spectrum of the reaction mixture of **1** with excess PMe₃ shows 4 absorptions (Table 5). The spectrum is consistent with a compound of the formula [(C₅Ph₅)Cr(CO)₃PMe₃][(C₅Ph₅)Cr(CO)₃].^{16,17} It is well established that 17e complexes tend to undergo substitution reactions via associative pathways.^{2d,7} Thus, a plausible reaction mechanism is shown in eq (2) and (3). When the reaction mixture is warmed to ambient temperature, **2** is produced quantitatively (eq 4). Further studies of this and similar low temperature reactions are underway.

PMePh₂ reacts with **1** at ambient temperature to yield solutions which display CO absorptions in the infrared where expected, but from which very little substitution product can be isolated. The following ligands do not react with **1** even at elevated temperatures (e.g. refluxing THF or benzene): PPh₃, P(OPh)₃, 2, 2'-bipyridine, and PhC≡CPh. The data for PMe₃, PMe₂Ph, and PMePh₂ suggest that steric effects are probably very important in the lack of reactivity of PPh₃ and P(OPh)₃.

Molecular Structure of (C₅Ph₅)Cr(CO)₂PMe₃•0.5THF. The X-ray crystal structure of (C₅Ph₅)Cr(CO)₂PMe₃•0.5THF is displayed in Figure 2. Bond distances and angles are listed in Tables 2 and 3, respectively. Phenyl dihedral angles are given in Table 4. There are two

conformers in the unit cell that do not differ in any chemically significant way. As in other, similar paramagnetic systems, the tripod angles deviate significantly from 90° .^{4,9a,e} Fortier and coworkers have reported calculations describing the origin of this effect.^{9e} The P atom lies below a C-C bond of the C_5 ring (a staggered conformation). $Cp^*Cr(CO)_2PMe_3$,^{9e} also adopts a staggered conformation, but for $CpCr(CO)_2PPh_3$ ^{9a} the P atom eclipses a carbon atom of the C_5 ring. As we will show below, the conformational energy difference for **2** is small, less than or on the order of kT at 200 K (0.02 eV). One further feature of the structure warrants comment. Elemental analysis, 1H NMR, and thermogravimetric analysis¹⁸ all support formulation of the solid phase as a monosolvate. Since all atoms in this structure were at full occupancy, it is likely that the structure was obtained of a rare crystal of an unrepresentative solvation number.

ESR Spectra. ESR spectra of **2**, **3**, and **4** in frozen toluene solution are rhombic with three distinct g -components. Spectra of **2** and **3** are shown in Figures 3 and 4. The spectrum of **4** is very similar to that of **2**. Interpretation of the spectra is straightforward, and the resulting parameters are given in Table 7(a). In all cases, the low-field features (g_{max}) are much broader than those corresponding to the two smaller g components. For **2** and **4**, the low-field features increase in width with increasing temperature whereas in spectra of **3**, these features are not as broad and sharpen slightly with increasing temperature. Spectra of **4** in dcm/dce were essentially identical to those in toluene except that the low-field features were broader and could not be located accurately, even at 125 K. These linewidth effects will be discussed elsewhere.¹⁹

The g -matrices have one component close to the free-electron g -value, g_e , a second component slightly larger than g_e , and a third component substantially larger than g_e . This pattern is characteristic of low-spin d^5 systems¹¹ and can be understood qualitatively in terms of a simple ligand-field theory model. The degeneracy of the octahedral ligand-field configuration, t_{2g}^5 , is lifted in lower symmetry, but strong spin-orbit coupling of the singly-occupied orbital (SOMO) with the other two components of the t_{2g} set leads to two g -components greater than g_e ; the third g -component differs from g_e through spin-orbit coupling with one of the e_g orbitals which is empty and at much higher energy. Although the spectra of $(C_5Ph_5)Cr(CO)_2L$ fit this

qualitative pattern, they exhibit a temperature-dependent linewidth effect which requires a more detailed analysis. Furthermore, the spectra in liquid solution at low temperatures are not isotropic but resemble the frozen solution spectra, albeit with significant shifts in the positions of features.

The complexes $(C_5Ph_5)Cr(CO)_2L$ have nominal C_s symmetry so that the SOMO could belong to either the a' or a'' representation. Previous work on related systems^{9e,20,21} and extended Hückel MO calculations¹⁹ suggest a SOMO of a'' symmetry. Taking xz as the plane of symmetry, the SOMO is given by eq (5).

$$|\text{SOMO}\rangle = a_1|xy\rangle + a_2|yz\rangle + \dots \quad (5)$$

Components of the g -matrix are given by eqs (6)¹¹ where, for example, $\delta_{x^2-y^2}$ is given

$$g_{xx} = g_e + 2[a_1^2 \delta_{xz} + a_2^2 (\delta_{x^2-y^2} + 3\delta_{z^2})] \quad (6a)$$

$$g_{yy} = g_e + 2(a_1^2 \delta_{yz} + a_2^2 \delta_{xy}) \quad (6b)$$

$$g_{zz} = g_e + 2(4a_1^2 \delta_{x^2-y^2} + a_2^2 \delta_{xz}) \quad (6c)$$

$$g_{xz} = -2a_1a_2(\delta_{xz} + 2\delta_{x^2-y^2}) \quad (6d)$$

by eq (7), in which ζ_{Cr} is the spin-orbit coupling constant for Cr, $E_0 - E_k$ is the energy of the k th

$$\delta_{x^2-y^2} = \zeta_{Cr} \sum_{k \neq 0} \frac{c_{k,x^2-y^2}^2}{E_0 - E_k} \quad (7)$$

MO relative to the energy of the SOMO, and c_{k,x^2-y^2} is the LCAO coefficient of $d_{x^2-y^2}$ in the k th MO. EHMO calculations¹⁹ suggest that the two highest doubly-occupied MO's, just below the SOMO in energy (the other members of the t_{2g} set), are predominantly $d_{x^2-y^2}$ and d_{z^2} in character so that $\delta_{xz}, \delta_{yz}, \delta_{xy} \ll \delta_{x^2-y^2}, \delta_z$; Thus g_{yy} is expected to be close to g_e , but the other components should be larger. The g -matrix is diagonalized by rotation about the y -axis by the angle β , given by eq (8), where $R = a_2/a_1$ and $Q = \delta_{z^2}/\delta_{x^2-y^2}$.

$$\tan 2\beta = \frac{-4R}{4 - R^2(1 + 3Q)} \quad (8)$$

The X and Z principal values of the g -matrix then are given by eq (9). Since experimentally, g_X is

$$g_{xz} = g_e + a_1^2 \delta_{x^2-y^2} \left[4 + R^2 (1 + 3Q) \right] \left\{ 1 \pm \sqrt{1 - \frac{48R^2Q}{\left[4 + R^2(1 + 3Q) \right]^2}} \right\} \quad (9)$$

close to g_e and g_z is much larger than g_e , the square root term of eq (9) is apparently close to 1.²² Spectra in liquid solution 10-20 K above the melting point of the solvent appear as approximately axial powder patterns. Spectra of **2** and **3** are shown in Figures 3 and 4; again the spectrum of **4** is qualitatively similar to that of **2**, with features significantly sharper than for **3**. In all cases, the features broaden at higher temperatures and eventually coalesce into a single broad line. Although the line narrows somewhat near room temperature, ³¹P splitting is never resolved. Parameters for the approximately axial spectra are given in Table 7(b).

The parallel features in the axial spectra are shifted upfield from the frozen solution g_z features and the perpendicular features are close to the position of the g_y features of the frozen solution spectra. At temperatures just above the melting point, the viscosity of toluene or dce/dcm is high, and it is not surprising that molecular rotation is too slow to produce an isotropic spectrum. Apparently there is some degree of averaging, however, such that the g_x and g_y features are merged and the g_z features somewhat shifted. The most likely explanation of this behavior is that the Cr(CO)₂L moiety is nearly freely rotating relative to the C₅Ph₅ group. In other words, the very bulky "seat" of the "piano stool" is essentially stationary on the ESR time scale while the "legs" rotate freely. The bulkier PMe₂Ph ligand would be expected to impede this averaging process, and features in the approximately axial spectra of **3** are significantly broader than those of **2** or **4**.

This behavior can be simulated using the program described by Schneider and Freed.²³ Shown in Figure 5 are computer simulations using the spin Hamiltonian parameters for **2** and a 5-Gauss Lorentzian linewidth. For the simulations in Figure 5a, isotropic rotational diffusion is assumed with $D_x = D_y = D_z$ ranging from 10⁷ to 5 × 10⁸ s⁻¹ whereas in Figure 5b, rotational diffusion is anisotropic with $D_x = D_y = 10^6$ s⁻¹ and D_z ranging from 10⁷ to 5 × 10⁸ s⁻¹. Although isotropic rotational diffusion can lead to an approximately axial spectrum, the parallel features

are very broad and both the parallel and perpendicular features shift significantly from the frozen solution positions. We can obtain an order-of-magnitude estimate of the isotropic rotational diffusion coefficients from eqs (10). Extrapolating literature values of the viscosity of

$$D = 1/6\tau_r \quad (10a)$$

$$\tau_r = V_h\eta/kT \quad (10b)$$

toluene²⁴ to 200 K, we obtain $\eta \approx 0.43 \text{ kg m}^{-1}\text{s}^{-1}$. Assuming that **2** is approximately spherical with a radius of about 7 Å, $\tau_r \approx 2 \times 10^{-7} \text{ s}$, $D \approx 7 \times 10^5 \text{ s}^{-1}$, about two orders of magnitude slower than required to obtain an approximately axial spectrum from isotropic motion.

On the other hand, anisotropic rotational diffusion with $D_x = D_y \ll D_z \approx 2 \times 10^8 \text{ s}^{-1}$ gives a reasonable account of the experimental results. This rate is considerably faster than might have been expected for rotational diffusion of the $\text{Cr}(\text{CO})_2\text{PMe}_3$ moiety in toluene at 200 K, ($D_z \approx 3 \times 10^7 \text{ s}^{-1}$, assuming a volume about 1/10 that of the whole complex and accounting for rotation about one axis). The most likely explanation is that the "piano-stool legs" rotate in a nearly solvent-free cavity created by the C_5Ph_5 ligand.

Assuming that anisotropic rotational diffusion is fast enough to completely average g_x and g_y , that the parallel axis corresponds to the Cr–Cp vector (the z -axis) and that the Z principal axis of the g -matrix differs from this axis by the angle β , the parallel and perpendicular components of the averaged g -matrix are given by eqs (11). These equations were used to compute the values of

$$2g_{\parallel}^2 = g_Z^2 + g_X^2 + (g_Z^2 - g_X^2)\cos^2 2\beta \quad (11a)$$

$$4g_{\perp}^2 = g_Z^2 + g_X^2 + 2g_Y^2 - (g_Z^2 - g_X^2)\cos^2 2\beta \quad (11b)$$

β listed in Table 8. Except for **4**, the agreement between values of β computed from g_{\parallel} —eq (11a)—and those computed from g_{\perp} —eq (11b)—is quite good, suggesting that the model is at least qualitatively correct. Extended Hückel MO calculations¹⁹ suggest that $Q \approx 1.4$; with this value, $\beta = 16^\circ$ and eq (8) give $R = -0.46$, in reasonable agreement with the EHMO prediction of 0.34. The values of beta listed in Table 8 also may be compared with those obtained from ESR

studies of $\text{CpCr}(\text{CO})_2\text{PPh}_3^{9c}$ and $(\text{C}_5\text{Me}_5)\text{Cr}(\text{CO})_2\text{PMe}_3^{9e}$ diluted into single crystals of the Mn analogs. For $\text{CpCr}(\text{CO})_2\text{PPh}_3$, four paramagnetic sites were found with slightly different principal values of the g -matrix and beta ranging from 3 to 8°; for $(\text{C}_5\text{Me}_5)\text{Cr}(\text{CO})_2\text{PMe}_3$, only one site was found with beta = 2.4°. These angles refer to the orientation of the g_{max} principal axis relative to the Mn-CNT axis in the host crystal and so may not be exactly equal to those relative to the Cr-CNT axis. Nonetheless, the angles are considerably smaller than those found in the present work; whether this reflects an error in our analysis or a true difference between the C_5Ph_5 ligand and the Cp and C_5Me_5 ligands is unclear.

Acknowledgments. The research at Marshall University was supported by the National Science Foundation (Grant NSF CHE-9123178) and the donors of The Petroleum Research Fund, administered by the American Chemical Society. The NSF provided funds towards the University of Delaware diffractometer. We thank Dr. R. J. Hoobler and Prof. J. W. Larson for experimental assistance, Dr. Michael Iglehart for obtaining and interpreting the TGAs, Prof. W. E. Geiger for helpful suggestions regarding both electrochemical experiments and interpretation of our results, Prof. J. H. Freed and Dr. R. Crepeau for supplying the ESR simulation program, and Prof. M. B. Zimmt for assistance in implementing the program at Brown.

Supporting Information Available. For $(\text{C}_5\text{Ph}_5)\text{Cr}(\text{CO})_2\text{PMe}_3 \cdot 0.5\text{THF}$ as follows: Table 1S, atomic coordinates and equivalent isotropic displacement coefficients, Table 2S, anisotropic displacement coefficients, Table 3S, hydrogen-atom coordinates, and a TGA of **2** (12 pages). Ordering information is given on any current masthead page.

- (12) Solutions at higher concentrations than normal were used because of the high air-sensitivity of the complexes in solution. Under the conditions employed, 0.5 mM solutions rarely maintained their integrity for more than a few minutes. Typical values of ΔE_p were in the range 150 - 180 mV. A 3 mM solution of $(C_5Ph_5)Cr(CO)_3$ gave the same $E^o(0/1^-)$ value as that reported for a much more dilute solution.⁴
- (13) It is interesting that Baird and coworkers do not report observing evidence of disubstitution reactions occurring in isoelectronic $CpCr(CO)_3$.⁶ While the large size of the C_5Ph_5 ligand probably precludes disubstitution in **1** for the ligands studied here, Baird's work suggests that a steric argument may not be necessary.

- (16) Two absorptions, 1892 and 1791 cm^{-1} , are associated with $(\text{C}_5\text{Ph}_5)\text{Cr}(\text{CO})_3$.⁴ The infrared spectrum of this complex is qualitatively similar to $[(\text{C}_5\text{Ph}_5)\text{Cr}(\text{CO})_2(\text{depe})]-[(\text{C}_5\text{Ph}_5)\text{Cr}(\text{CO})_3]$ (Jarrell, C. S.; Castellani, M. P. unpublished results).
- (17) To our knowledge no such Cr complexes are known, however, several similar Mo complexes have been isolated. The infrared spectra of the Mo complexes are very similar to those obtained for the Cr system. (a) Nolte, M. J.; Reimann, R. H. *J. Chem. Soc., Dalton Trans.* **1978**, 932. (b) Asdar, A.; Tudoret, M.-J.; Lapinte, C. *J. Organomet. Chem.* **1988**, 349, 353.
- (18) A TGA of this compound shows that the complex loses its THF solvate well before decomposition begins. Desolvation begins at *ca.* 150 °C and results in the crystals losing their luster with no significant decoloration occurring. Complexes **3** and **4** undergo similar visual changes for, presumably, the same reason. A copy of the TGA of **2** is provided in the Supplementary Material.
- (19) Castellani, M. P.; Connelly, N. G.; Rieger, A. L.; Rieger, P. H. to be published.
- (20) Morton, J. R.; Preston, K. F.; Cooley, Baird, M. C.; Krusic, P. J.; McLain, S. J. *J. Chem. Soc., Faraday Trans. I* **1987**, 83, 3535.
- (21) Pike, R. D.; Rieger, A. L.; Rieger, P. H. *J. Chem. Soc., Faraday Trans. I* **1989**, 85, 3913.
- (22) Since EHMO calculations¹⁹ suggest that *R* is negative and *Q* is positive, eq (9) predicts g_z , $g_x > g_e$. The observed values of g_x , *ca.* 1.994, suggest that the δ_{xz} terms in eqs (6) are not entirely negligible.

Table 1. Crystal and Refinement Data for (C₅Ph₅)Cr(CO)₂PMe₃•0.5THF

a. Crystal Data

formula	C ₄₀ H ₃₄ CrO ₂ P
fw	629.6
cryst system	Triclinic
space group	$P\bar{1}$
<i>a</i> , Å	12.834(2)
<i>b</i> , Å	13.271(3)
<i>c</i> , Å	22.536(5)
α, deg	90.96(2)
β, deg	94.29(2)
γ, deg	112.55(1)
<i>V</i> , Å ³	3530.6(12)
<i>Z</i>	4
color	dark red
crystal size, mm	0.44 x 0.58 x 0.74
<i>D</i> (Calcd), g/cm ³	1.185
abs coeff, cm ⁻¹	0.401 mm ⁻¹

b. Data Collection

diffractometer	Siemens P4
radiation	MoKα (λ = 0.710 73 Å)
temp, K	293
2θ scan range, deg	1.00°
scan type	Wycoff
reflns collcd	14234
obsd rflns	6465 ($F > 5.0\sigma(F)$)

c. Solution and Refinement

solution	direct methods
refinement method	full-matrix least-squares
quantity minimized	$\Sigma w(F_o - F_c)^2$
weighting scheme	$w^{-1} = \sigma^2(F) + 0.0015F^2$
number of parameters refined	838
final <i>R</i> indices (obs. data),%	<i>R</i> = 5.62, <i>wR</i> = 6.67
<i>R</i> indices (all data), %	<i>R</i> = 12.75, <i>wR</i> = 8.93
GOF	1.11
data-to-parameter ratio	7.7:1
largest difference peak, eÅ ⁻³	0.34
largest difference hole, eÅ ⁻³	-0.39

**Substitution Reactions of $(C_5Ph_5)Cr(CO)_3$: Structural, Electrochemical, and Spectroscopic
Characterization of $(C_5Ph_5)Cr(CO)_2L$, $L = PMe_3, PMe_2Ph, P(OMe)_3$**

D. John Hammack, Mills M. Dillard, Michael P. Castellani,* Arnold L. Rheingold,*
Anne L. Rieger, and Philip H. Rieger*

The series of compounds $(C_5Ph_5)Cr(CO)_2L$ ($L = PMe_3, PMe_2Ph, P(OMe)_3$) have been prepared and characterized by IR, NMR, and ESR spectroscopies, cyclic voltammetry, and X-ray crystallography ($L = PMe_3$). Frozen solution ESR studies and extended Hückel molecular orbital calculations suggest the $Cr(CO)_2L$ moiety freely rotates relative to the C_5Ph_5 ligand.
